Introduction

Parallel Storage Systems

2025-04-07

Prof. Dr. Michael Kuhn
michael.kuhn@ovgu.de

Parallel Computing and I/O
Institute for Intelligent Cooperating Systems
Faculty of Computer Science
Otto von Guericke University Magdeburg
https://parcio.ovgu.de

Outline

Introduction

- Organization
- Lecture
- Exercises
- Overview
- Summary

- Have you heard our lecture on parallel programming?
  1. Yes
  2. No

- How familiar are you with C?
  1. Expert
  2. Advanced
  3. Beginner
  4. Not at all

Survey

- How familiar are you with Linux?
  1. Expert
  2. Advanced
  3. Beginner
  4. Not at all

Survey

- How familiar are you with Git?
  1. Expert
  2. Advanced
  3. Beginner
  4. Not at all

Lecture and Exercises

- Lecture: Mondays, 9:15–10:45
  - We will also use this time slot to clear up questions etc.
- Exercises: Thursdays, 13:15–14:45
  - We will discuss solutions and take a look at the next exercise sheet
  - Attendance is mandatory and everyone has to present at least once
  - You need at least 50 % of the overall points to pass the exercises
- Exam: Oral

Communication

- Please sign up for the Mattermost team
  - If there are questions about the lecture or exercises, please ask them there
  - Feel free to use it for discussion and communication with your fellow students
    - You can also use it to find people for your exercise group
  - You can of course also send us e-mails:
    - michael.kuhn@ovgu.de (lecture and general)
    - michael.blesel@ovgu.de (exercises)
- Slides, exercise sheets etc. will be available on the website

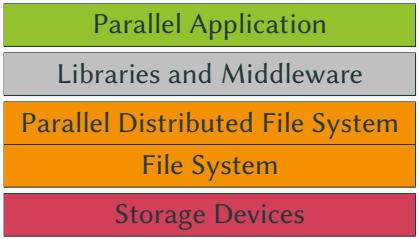
- High Performance Parallel I/O (Prabhat, Quincey Koziol); October 23, 2014 by Chapman and Hall/CRC; ISBN 9781466582347
- Understanding the Linux Kernel (Daniel P. Bovet, Marco Cesati)
- Professional Linux Kernel Architecture (Wolfgang Maurer)

Outline

Introduction

- Organization
- Lecture
- Exercises
- Overview
- Summary

- Storage stack is layered
  - Many different components are involved
  - Performance problems influence all layers
- Complex interactions
  - Optimizations and workarounds on all layers
  - Information about other layers required
- Data transformation
  - Data is transported through all layers
  - Loss of high-level information



- Introduction (today ☺)
  - This is an overview of the most important parallel concepts
- Storage Devices
  - Performance characteristics, storage arrays, reliability etc.
- File Systems
  - General file system concepts and data structures
- Modern File Systems
  - More advanced functionality such as copy-on-write, checksums etc.

- Parallel Distributed File Systems
  - Parallel and distributed concepts, performance considerations
- MPI-IO
  - Concepts for parallel I/O, interface and functionality
- Libraries
  - Overview of different I/O libraries
- Optimizations
  - Basics of performance optimization, different approaches

- Performance Analysis
  - How to measure and assess I/O performance
- Data Reduction
  - Overview of data reduction considerations and techniques
- Future Developments
  - Upcoming storage hardware and software approaches
- Research Talks
  - Research topics currently investigated in our group

Outline

Introduction

- Organization
- Lecture
- Exercises
- Overview
- Summary

- Exercises will require some programming in (preferably) a systems language
  - Trying out the concepts taught in the lecture
- You should have experience in a programming language
  - Experience in C is not necessary (but helps)
- We will mostly work on our cluster via SSH
  - Some exercises can also be done on your own computer
  - Logging in and setting everything up will be part of the first exercise

- Introduction
  - Set up development environment and C introduction
- Debugging and Checkpoints
  - Debugging C code and reading/writing data
- I/O Tools
  - Using tools to analyze and optimize I/O performance

- Dummy File System
  - Introduction to file system interface using FUSE
- Memory File System
  - Extend dummy file system to store data in memory
- Persistent File System
  - Develop a design for a persistent file system
  - Extending memory file system to persist data

Outline

Introduction

- Organization
- Lecture
- Exercises
- Overview
- Summary

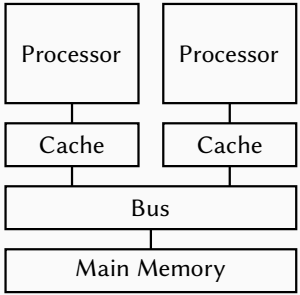
Motivation

- Parallel programming is an important skill
  - Processors feature an increasing amount of cores
  - Even current phones have eight cores
- Serial applications will not be able to fully utilize a machine
  - Except for cases we call trivial parallelization
  - Sometimes possible to run multiple serial applications in parallel
- Parallelization is very important in science
  - Many problems can only be solved on supercomputers
  - High-performance computing (HPC)

- Until ca. 2005: Performance increase via clock rate
  - Going from n GHz to 2n GHz will usually double application performance
- Since ca. 2005: Performance increase via core count
  - Clock rate cannot be increased further
  - Power consumption/heat depends on clock rate
  - Biggest supercomputers on TOP500 list have more than 10,000,000 cores
- Important classification: Memory access model
  - Shared and distributed memory
  - In reality, typically hybrid systems

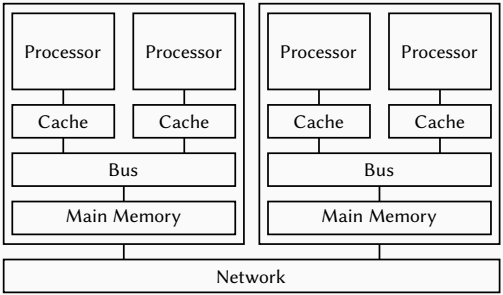
Hardware Architectures...

- All processors have access to shared memory
  - There might be speed differences due to NUMA
- Typically refers to single machines
  - Shared memory can also be virtual
- Processors consist of multiple cores
  - Each core has its own caches
  - Shared cache for the whole processor
- Access to shared memory via a bus
  - This also limits scalability of shared memory



Hardware Architectures...

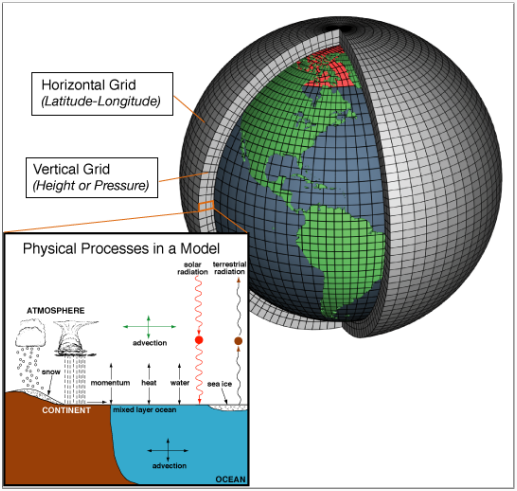
- Processors only have access to own memory
  - Typically with shared memory architecture
- Typically refers to a cluster of machines
  - Could theoretically be used inside machine
- Machines are connected via a network
  - Determines scalability and performance
  - Different network technologies and topologies



- Parallel programming is used to increase application performance
  - In HPC, OpenMP and MPI are often used together
- OpenMP is an interface for shared memory
  - Applications run as multiple threads within a single process
  - OpenMP features thread management, task scheduling, synchronization and more
- MPI (Message Passing Interface) is an interface for distributed memory
  - Applications run distributed over multiple compute nodes
  - MPI features message passing, input/output and other functions
- Both approaches are available for multiple programming languages

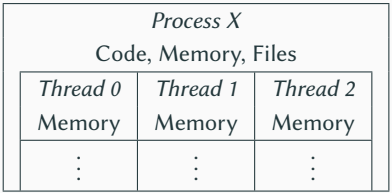
Parallel Programming...

- Numerical problems are mostly iterative
  - Simulations often performed in time steps
- Global conditions for termination
  - Run for a specified number of time steps
- Data structures are often regular
  - Data often stored in one or more matrices
- Many phenomena are highly parallel
  - Galaxies, planets, climate and weather
- Parallel computing is well-suited
  - Data and components can be distributed



[NOAA, 2007]

Parallel Programming...



- We will only take a look at threads for now
  - Message passing will be covered later
- Processes are instances of an application
  - Applications can be started multiple times
  - Processes are isolated from each other by the operating system
  - Resources like allocated memory, opened files etc. are managed per-process
- Threads are lightweight processes
  - Threads have their own stacks but share all other resources
  - Shared access to resources has to be synchronized
  - Uncoordinated access can lead to errors very easily

Parallel Programming...

- Threads share a common address space
  - Communication is often done via shared variables
  - Threads are processed independently, that is, in parallel
  - If one thread crashes, the process crashes with all threads
- Processes have their own address spaces
  - Typically have to start multiple processes for distributed memory
  - Overhead is normally higher than with shared memory
  - There are also concepts for distributed shared memory
- In practice, hybrid approaches are used
  - A few processes per node (e. g., one per socket)
  - Many threads per process (e. g., one per core)

- Numerical applications often deal with matrices
  - Matrices are as big as the main memory allows
  - We want to calculate the sum of all elements
- Have to go through all rows and columns
  - Process one element after the other

(0,0)	(0,1)	...	(0,n-1)	(0,n)
...	...	...	...	...
(m,0)	(m,1)	...	(m,n-1)	(m,n)

```
1 for (int i = 0; i < m; i++) {
2     for (int j = 0; j < n; j++) {
3         sum += arr[i][j];
4     }
5 }
```

Parallelization with OpenMP...

- OpenMP allows parallelization using compiler pragmas
  - Very convenient for developers, no internal knowledge necessary
  - Reduced functionality when compared to system-level approaches

```
#pragma omp parallel for
for (int i = 0; i < m; i++) {
    for (int j = 0; j < n; j++) {
        sum += arr[i][j];
    }
}
```

Parallelization with OpenMP...

```
1 for (int i = 0; i < m/2; i++) {
2     for (int j = 0; j < n; j++) {
3         sum += arr[i][j];
4     }
5 }
```

```
1 for (int i = m/2; i < m; i++) {
2     for (int j = 0; j < n; j++) {
3         sum += arr[i][j];
4     }
5 }
```

- First for loop is split up across multiple threads
  - Usually as many threads as there are cores
  - OpenMP can also do dynamic distributions and further scheduling
- Example: Laptop with two cores
  - First core calculates `0` to `(m/2)-1`
  - Second core calculates `m/2` to `m-1`

Parallelization with OpenMP...

- This solution was very easy but also wrong ☺
  - Instead of the correct sum, we get weird values
  - Every time we run the application, the result changes

```
$ ./openmp
sum=3773725
$ ./openmp
sum=4012997
$ ./openmp
sum=12325088
$ ./openmp
sum=2456866
$ ./openmp
sum=11970989
$ ./openmp
sum=2818054
$ ./openmp
sum=3979092
```

Parallelization with OpenMP...

- This solution was very easy but also wrong ☺
  - Instead of the correct sum, we get weird values
  - Every time we run the application, the result changes
- Shared memory makes it easy to access the sum variable
  - Access has to be synchronized, otherwise errors occur
  - We have produced a so-called race condition
- There are several possibilities to solve the problem
  - Add a lock around the operation (slow)
  - Use atomic instructions (fast)

```
$ ./openmp
sum=3773725
$ ./openmp
sum=4012997
$ ./openmp
sum=12325088
$ ./openmp
sum=2456866
$ ./openmp
sum=11970989
$ ./openmp
sum=2818054
$ ./openmp
sum=3979092
```

Debugging

- Parallel programming has at least two new error classes
  1. Deadlocks
  2. Race conditions
- A race condition has resulted in a wrong result in our example
  - Incrementing a variable consists of three operations
    1. Loading the variable
    2. Modifying the variable
    3. Storing the variable
  - Operations have to be performed atomically

- Parallel programming has at least two new error classes
  1. Deadlocks
  2. Race conditions
- A race condition has resulted in a wrong result in our example
  - Incrementing a variable consists of three operations
    1. Loading the variable
    2. Modifying the variable
    3. Storing the variable
  - Operations have to be performed atomically

T0	T1	V
Load 0		0
Inc 1		0
Store 1		1
	Load 1	1
	Inc 2	1
	Store 2	2

- Parallel programming has at least two new error classes
  1. Deadlocks
  2. Race conditions
- A race condition has resulted in a wrong result in our example
  - Incrementing a variable consists of three operations
    1. Loading the variable
    2. Modifying the variable
    3. Storing the variable
  - Operations have to be performed atomically

T0	T1	V
Load 0		0
Inc 1		0
Store 1		1
	Load 1	1
	Inc 2	1
	Store 2	2

T0	T1	V
Load 0		0
Inc 1	Load 0	0
Store 1	Inc 1	1
	Store 1	1

Debugging...

- Deadlocks cause parallel applications to stop progressing
  - Can have different causes, most often due to locking
  - May not be reproducible if there is time-dependent behavior
- Error condition can be difficult to find
  - Trying to lock an already acquired lock results in a deadlock
  - Erroneous communication patterns (everyone waits for the right neighbor)
- Error effect is typically easy to spot
  - Spinlocks or livelocks can look like computation, though

Debugging...

- Race conditions can lead to differing results
  - Debugging often hides race conditions
- Error condition is often very hard to find
  - Can be observed at runtime or be found by static analysis
  - Modern programming languages like Rust can detect data races
- Error effect is sometimes not observable
  - Slight variations in the results are not obvious
  - The correct result cannot be determined for complex applications
  - Repeating a calculation can be too costly

Networking Aspects

- Scalability of shared memory systems is limited
  - Current processors feature up to 64 cores with 128 threads
  - Typically two, at most four processors per node
- Computation is only one part of parallel applications
  - They need to store data in main memory and persist it to storage
  - Amount of main memory and storage per node is also limited
- To solve the biggest problems, we need distributed memory systems
  - These typically consist of a cluster of shared memory systems
  - Multiple nodes are connected via a so-called interconnect

Networking Aspects...

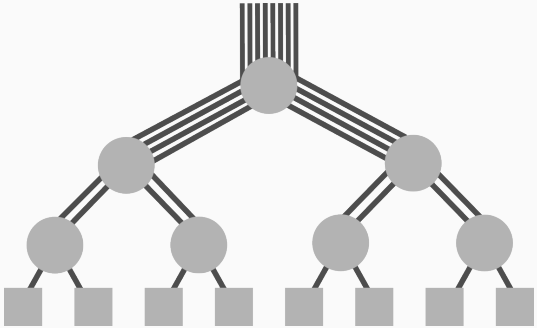
- Processors require data fast
  - 3 GHz equals three operations per nanosecond
  - Even accessing the main memory is too slow
  - Multiple cache levels hide main memory latency
- Network and I/O extremely slow in comparison
  - Waiting for an HDD ruins performance
  - SSDs have alleviated the problem a bit

Level	Latency
L1 cache	≈ 1 ns
L2 cache	≈ 5 ns
L3 cache	≈ 10 ns
RAM	≈ 100 ns
InfiniBand	≈ 500 ns
Ethernet	≈ 100,000 ns
SSD	≈ 100,000 ns
HDD	≈ 10,000,000 ns

[Bonér, 2012] [Huang et al., 2014]

Networking Aspects...

- Network topologies can get quite complex
  - Easy: All nodes are connected to one switch
- Larger systems use hierarchical topologies
  - A fat tree has different throughputs depending on the tree level
- Fat trees can also have blocking factor (2:1)
  - Nodes in enclosure communicate at 100 %
  - Enclosures in rack communicate at 50 %
  - Racks communicate at 25 %



[Solnushkin, 2012]

Networking Aspects...

- Current network technologies feature high throughputs
  - InfiniBand can do up to 600 GBit/s
  - Ethernet can do up to 400 GBit/s
  - There are more technologies like Intel's Omni-Path
- Sophisticated approaches required to reach these high speeds
  - Kernel bypass to save context switches
  - Zero copy to avoid exhausting bus speeds

- Parallel applications can be run across multiple nodes
  - Typically as separate processes, requires message passing
  - MPI is the de-facto standard
- MPI offers operations for communication and more
  - Process groups and synchronization
  - Sending, receiving, reduction etc.
  - Point-to-point, collective or one-sided communication
- MPI also supports parallel I/O
  - Concurrent access to shared files

- Parallel application now runs as two independent processes
  - Processes can only see their own results, no shared memory
  - There is no risk of overwriting other values as in the OpenMP example
  - However, results have to be communicated between processes somehow

```
1 for (int i = 0; i < m/2; i++) {
2     for (int j = 0; j < n; j++) {
3         sum += arr[i][j];
4     }
5 }
```

```
1 for (int i = m/2; i < m; i++) {
2     for (int j = 0; j < n; j++) {
3         sum += arr[i][j];
4     }
5 }
```

Programming with MPI...

- MPI allows us to perform efficient reduction operations
  - A predefined reduction operation is the sum

```
1  MPI_Init(NULL, NULL);
2  for (int i = 0; i < m/2; i++) {
3      for (int j = 0; j < n; j++) {
4          sum += arr[i][j];
5      }
6  }
7  MPI_Allreduce(&sum, &allsum, 1,
8                MPI_INT, MPI_SUM,
9                MPI_COMM_WORLD);
10 MPI_Finalize();
```

```
1  MPI_Init(NULL, NULL);
2  for (int i = m/2; i < m; i++) {
3      for (int j = 0; j < n; j++) {
4          sum += arr[i][j];
5      }
6  }
7  MPI_Allreduce(&sum, &allsum, 1,
8                MPI_INT, MPI_SUM,
9                MPI_COMM_WORLD);
10 MPI_Finalize();
```

Programming with MPI...

- Application code is typically still contained in one file
  - MPI allows us to write a generic version of the application
  - We can determine our rank and the number of processes

```
1  MPI_Init(NULL, NULL);
2  MPI_Comm_rank(MPI_COMM_WORLD, &rank);
3  MPI_Comm_size(MPI_COMM_WORLD, &size);
4  for (int i = (m/size) * rank; i < (m/size) * (rank + 1); i++) {
5      for (int j = 0; j < n; j++) {
6          sum += arr[i][j];
7      }
8  }
9  MPI_Allreduce(&sum, &allsum, 1, MPI_INT, MPI_SUM, MPI_COMM_WORLD);
10 MPI_Finalize();
```

Scalability

- When writing parallel applications, we must consider scalability
  - Scalability describes how an application behaves with increasing parallelism
- HPC systems are usually very expensive and should be used accordingly
  - Procurement costs can reach up to € 250,000,000
- To determine scalability, we have to analyze performance
  - HPC systems are complex, performance yield is often not optimal
  - Many different components interact with each other
    - Processors, caches, main memory, network, storage system etc.

Scalability...

- In addition to procurement costs, operating is also quite expensive
  - 1. Frontier (USA): 1.2 EFLOPS at 22.7 MW ≈ € 52,700,000/a (in Germany)
  - 5. LUMI (Finland): 380 PFLOPS at 7.1 MW ≈ € 16,500,000/a (in Germany)
  - 74. Levante (Germany): 10 PFLOPS at 2 MW ≈ € 4,600,000/a
- Communication and I/O are often responsible for performance problems
  - High latency, which causes excessive waiting times for processors
  - Communication and I/O typically happen synchronously

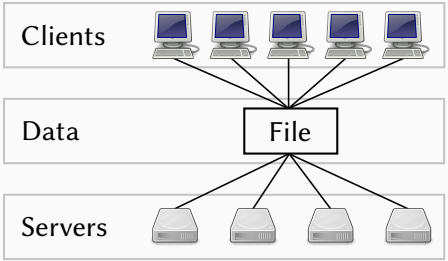
Scalability...

- The performance improvement we get is called speedup
  - In the best case, the speedup is equal to the number of threads
  - In reality, the speedup is usually lower due to overhead
- Speedup can sometimes be higher than the number of threads
  - This is called a superlinear speedup and usually points at a problem
  - For example, each thread's data suddenly fits into the cache
    - This means that the measured problem became too small
    - Larger problems will not fit and therefore have a lower speedup

- Applications typically need input data and produce output data
  - I/O is an important aspect and can be relevant for overall performance
  - Without I/O, the results of a scientific application would be lost
- Applications often run for multiple days or weeks
  - To cope with crashes, it is necessary to write checkpoints
  - Jobs are often only allowed to run for a few hours at a time
- As mentioned before, storage devices have high latencies
  - Waiting for I/O usually impacts performance negatively
  - File systems try to cache data aggressively to hide latency

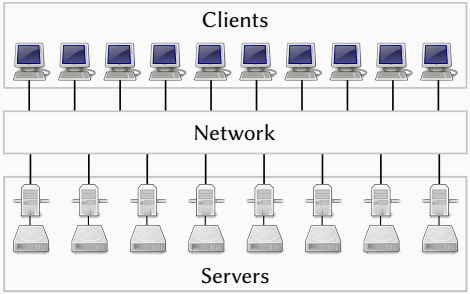
Parallel I/O...

- Access via parallel distributed file systems
  - Allow concurrent access from clients
  - Distribute data across servers
- Clients can access a shared file
  - Everyone can read input and write results
  - Necessary for parallel applications
- Servers share the load
  - Files are split up and distributed
  - Use capacity and throughput of many servers



Parallel I/O...

- Computation and storage usually separated
  - Can be optimized for respective workloads
  - No interference of other components
- Clients run parallel applications
  - Small local storage for OS and caching
  - Access to the file system via the network
  - No direct access to file system's devices
- Servers store data and metadata
  - Typically servers with many HDDs and SSDs



Outline

Introduction

- Organization
- Lecture
- Exercises
- Overview
- Summary

- Parallel programming is an important skill
  - Current computers always have multiple cores or processors
- Parallelization is used to improve performance
  - It is necessary to understand the hardware and keep scalability in mind
- Shared memory and distributed memory are the two main architectures
  - Threads can be used for shared memory systems
  - Message passing is often used for distributed memory systems
- Parallel applications can have deadlocks and race conditions
  - These errors can be hard to find and non-deterministic
- Parallel I/O is an important part of parallel applications
  - I/O is necessary to read input data and store results
